# On Digraphs under $x^{2}$ and $x^{2}-2$ modulo a Mersenne Prime 

Tony Reix (tony.reix@laposte.net)<br>ZetaX (AOPS forum)<br>maxal (GIMPS forum)<br>2006, 13th of May (updated: 2007, 11th of April)

This paper presents how two theorems dealing with the Lucas-Lehmer Test for Mersenne numbers (LLT) were found and proven.
These theorems deal with computing the number of cycles of length $L$ that appear in a Digraph under $x^{2}$ or $x^{2}-2$ modulo a Mersenne prime $M_{q}=2^{q}-1$, where $q$ is prime and $L \mid q-1$.

## 1 Introduction

The Lucas-Lehmer Test says that a Mersenne number $M_{q}=2^{q}-1$ (where $q$ is prime) is prime iff $M_{q} \mid S_{q-2}$, where $S_{0}=4, S_{i+1}=S_{i}^{2}-2$.
Let call llt the function: llt: $x \mapsto x^{2}-2 \bmod M_{q}$.
Let call $l l t^{\perp}$ the function: $l l t^{\perp}: x \mapsto x\left(x^{2}-3\right) \bmod M_{q}$.
Let $S$ be the finite set defined by: $S=\left\{x\right.$ integer $\left.; 0 \leq x<M_{q}\right\}$ and let: $f: S \mapsto S$ be a function.

We define a directed graph $G_{f}$ whose vertices are given by the elements of $S$ and whose directed edges are $(x, f(x))$ for each $x \in S$.

## 2 Previous personal experimental research

Long time ago, I studied the topology of $G_{l l t}$.
I (re)discovered that the structure of the digraph $G_{l l t}$ is made of:
One Tree: one reversed complete binary tree of height $q-1$ ending in 0 , attached to the node -2 attached to the node 2 with a cycle of length 1 , where the $2^{q-2}$ roots of the tree are all the numbers built by: $R_{0}=4, R_{i+1}=$ $l l t^{\perp}\left(R_{i}\right)$; and:
Cycles: a set of cycles of length $L$ dividing $q-1$.
The existence and some properties of the Tree are well-known and proven. But at that time I found no study of the properties of the Cycles.

I computed the number of cycles of length $L$ for $q=3,5,7,13,17,19,31$, as shown in Table 9 , by means of a C program that computes all pairs ( $x, x^{2}-2$ $\left.\left(\bmod M_{q}\right)\right)$, finds the cycles and counts cycles of same length.

Table 1: Number of loops of length $L$ under $x^{2}-2$ modulo the first Mersennes.

## 3 Example with $q=5$

The Figure 1 shows the tree and cycles for $q=5$.
As shown in table 9, there are two cycles of length $1:(2 \leftrightarrow 2)$ and $\left(M_{5}-1 \leftrightarrow\right.$ $\left.M_{5}-1\right)$, one cycle of length 2: $(12 \rightarrow-13 \rightarrow 12)$, and one cycle of length 4: $(3 \rightarrow 7 \rightarrow-15 \rightarrow 6 \rightarrow 3)$.

## 4 A problem by Daniel Shanks

Later, I discovered that Daniel Shanks, in his book "Solved and Unsolved Problems in Number Theory" (1962 Edition), has already studied the topology of the Digraph $G_{l l t}$.
Page 215, in Chapter "Supplementary Comments, Theorems, and Exercises", Shanks provides the complete Digraph $G_{l l t}$ for $q=5$, plus several useful properties. At the end of the page, he asked the reader to: "Develop a general theory for all prime $M_{p}$, proving the main theorems, if you can".
But he provided no hints !

## 5 Quadratic maps over $G F(p)$

In their paper: "On the iteration of certain quadratic maps over $G F(p)$ ", Troy Vasiga and Jeffrey Shallit consider the properties of certain graphs

Figure 1: Tree and Cycles under $x^{2}-2$ modulo $M_{5}$.
based on iteration of the quadratic maps $x \rightarrow x^{2}$ and $x \rightarrow x^{2}-2$ over a finite field $G F(p)$.
They provide several interesting theorems about the tails and cycles of the iterations $x \rightarrow x^{2}$ and $x \rightarrow x^{2}-2$ modulo any prime.
They also focus on Fermat and Mersenne primes, proving the following theorems:

Theorem 1 (5) When $p=2^{q}-1$, a Mersenne prime, the digraph $G_{x \rightarrow x^{2}}$ consists of cycles whose length divides $q-1$. Off each element in these cycles there hangs a single element with tail length 1.

Corollary 1 (3) Let $p$ be an odd prime with $p-1=2^{\tau} \cdot \rho, \rho$ odd. For each positive integer divisor $d$ of $\rho, G_{x \rightarrow x^{2}}$ contains $\varphi(d) /\left(o r d_{d} 2\right)$ cycles of length $\operatorname{ord}_{d} 2$. There are $\rho$ elements in all these cycles, and off each element in these cycles there hang reversed complete binary trees of height $\tau-1$ containing $2^{\tau}-1$ elements.

Theorem 2 (17) When $p=2^{q}-1$, a Mersenne prime, the digraph $G_{x \rightarrow x^{2}-2}$ consists of
(i) A reversed complete binary tree of height $q-1$ with root 0 , attached to the node -2 , which is attached to the node 2 with a cycle of length 1 on this
node. The nodes in this tree are given by $\theta^{n}+\theta^{-n}, 0 \leq n \leq 2^{q-1}$, where $\theta$ is a zero of $X^{2}-4 X+1$.
(ii) A set of cycles of length dividing $q-1$. Off each element in these cycles there hangs a single element with tail length 1. The nodes in these cycles are given by $3^{n}+3^{-n}, 1 \leq n \leq 2^{q-1}-2$.

Corollary 2 (15) Let $p$ be an odd prime with $p-1=2^{\tau} \cdot \rho, p+1=2^{\tau^{\prime}} \cdot \rho^{\prime}$, $\rho, \rho^{\prime}$ odd. For each divisor $d>1$ of $\rho, G=G_{x \rightarrow x^{2}-2}$ contains $\varphi(d) /\left(2\right.$ ord $\left._{d}^{\prime} 2\right)$ cycles of length ord $d_{d}^{\prime} 2$. There are $\rho$ elements in all these cycles, and off each element in these cycles there hang reversed complete binary trees of height $\tau-1$ containing $2^{\tau}-1$ elements.
Similarly, for each divisor $d^{\prime}>1$ of $\rho^{\prime}$, there exists $\varphi\left(d^{\prime}\right) /\left(2\right.$ or $\left.d_{d^{\prime}}^{\prime} 2\right)$ cycles of length ord $d_{d^{\prime}}^{\prime} 2$ and off each element in these cycles there hang reversed complete binary trees of height $\tau^{\prime}-1$ containing $2^{\tau^{\prime}}-1$ elements.
Finally, the element 0 is the root of a complete binary tree of height $\tau-2$ (respectively $\left.\tau^{\prime}-2\right)$ when $p \equiv 1(\bmod 4)($ respectively $p \equiv 3(\bmod 4)$ ), and $G$ also contains the directed edges $(0,-2),(-2,2),(2,2)$.

## $6 \quad L$ is independent of $q$ under $x^{2}$ modulo $M_{q}$

Thanks to Shallit's formula, I wrote a PARI/gp program that enabled me to compute the number of cycles under $x^{2}$ modulo a Mersenne prime $M_{q}$ for: $q=5,7,13,17,19,31,61,89,107,127$, providing one or several values for each $L$ from 1 to 12 , and $14,15,18,20,21,22,30,42,44,53,60,63,88,106,126$.

Since all values found for each $L$ were identical whatever the value of $q$, I guessed that the number of cycles of length $L$ under $x^{2}$ modulo a Mersenne prime $M_{q}$ does NOT depend on $q$.
The number of cycles of length $L$ for $L=1 . .12^{+}$is shown in table 2 .

| L | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 14 | 15 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $\psi(L)$ | 1 | 1 | 2 | 3 | 6 | 9 | 18 | 30 | 56 | 99 | 186 | 335 | 1161 | 2182 |

Table 2: Number of cycles of length $L$ under $x^{2}$ for $L=1 . .12^{+}$.

Here is the PARI/gp program which enabled to compute table 2.

```
VS(q) = {
```

```
    cyc = divisors(q-1);
    lencyc = vector(q-1);
    fac = divisors(2^(q-1)-1);
    l = length(fac);
    for(i=2, l,
        or = znorder(Mod(2, fac[i]));
        ep = eulerphi(fac[i]);
        lencyc[or] += ep/or;
    );
    for(i=1, q-1,
        if(lencyc[i] != 0,
            print(i, " ", lencyc[i]);
        );
    );
}
```

As an example, the number of cycles of length $L$ under $x^{2}$ for $q=127$ is given by table 3 .

| L | $\psi(L)$ |
| ---: | ---: |
| 1 | 1 |
| 2 | 1 |
| 3 | 2 |
| 6 | 9 |
| 7 | 18 |
| 9 | 56 |
| 14 | 1161 |
| 18 | 14532 |
| 21 | 99858 |
| 42 | 104715342801 |
| 63 | 146402730743693304 |
| 126 | 675163426430433459179525995420973028 |

Table 3: Number of cycles of length $L$ under $x^{2}$ modulo $2^{127}-1$.

## 7 OEIS A001037

The OEIS (The On-Line Encyclopedia of Integer Sequences!) is aimed at helping people to check if a sequence of integers is already known or not.

Typing the sequence: $1,1,2,3,6,9,18,30,56,99,186,335$ on page:
http://www.research.att.com/~njas/sequences/index.html, I was able to check that my sequence from 1 to 12 was identical to the beginning of sequence A001037, and that the other values of my sequence matched the A001037 sequence:
$[1,2,1,2,3,6,9,18,30,56,99,186,335,630,1161,2182,4080,7710,14532,27594$, 52377, 99858, 190557, 364722, 698870, 1342176, 2580795, 4971008, 9586395, 18512790, 35790267, 69273666, 134215680, 260300986, 505286415, 981706806] .

This sequence is defined as:
"Number of degree-n irreducible polynomials over $G F(2)$ ", or:
"Number of n-bead necklaces with beads of 2 colors when turning over is not allowed and with primitive period n" or:
"Number of binary Lyndon words of length n."
See: http://www.research.att.com/~njas/sequences/A001037.
And this sequence is built by the formula:

$$
A 001037(n)=\frac{1}{n} \sum_{d \mid n} \mu\left(\frac{n}{d}\right) 2^{d}
$$

## 8 Art Of Problem Solving forum - ZetaX

Then, on the "Art of Problem Solving" forum, I asked if someone were able to prove that $\psi(L)=A 001037(L)$.

ZetaX
 quickly provided the theorems and their proofs, as described in next section.

See: http://www.artofproblemsolving.com/Forum/forum-6.html.

## $9 \quad$ Cycles under $x^{2} \bmod$ a Mersenne prime

Theorem 3 (ZetaX-1) The number of cycles of length $L$ ( $L$ divides $q-1$ ) in the digraph $G_{x \rightarrow x^{2}}$ modulo a Mersenne prime $2^{q}-1$ is:

$$
\psi(L)=\frac{1}{L} \sum_{d \mid L} \mu\left(\frac{L}{d}\right) 2^{d}
$$

Proof:
By the existence of a primitive root modulo $2^{q}-1$, we can see it also as the following problem: Find the number of cycles of length $l$ under the action $x \rightarrow 2 x$ seen modulo $2^{q}-2$.
Now canonically lets find the number of solutions of $2^{n} x \equiv x\left(\bmod 2^{q}-\right.$ $2) \Longleftrightarrow\left(2^{n}-1\right) x \equiv 0\left(\bmod 2^{q}-2\right)$, since this is the number of $x$ that are part of a cycle having an order dividing $n$.
Since $\operatorname{gcd}\left(2^{q}-2,2^{n}-1\right)=2^{\operatorname{gcd}(q-1, n)}-1$, we have only to consider $n$ that divides $q-1$ and there are $2^{n}-1$ solutions then.
Let $\psi(l)$ be the number of elements of cycles of exactly length $l$.
Now we have $2^{n}-1=\sum_{d \mid n} \psi(d)$. By the Moebius-inversion-formula, we get:

$$
\psi(n)=\sum_{d \mid n} \mu\left(\frac{n}{d}\right)\left(2^{d}-1\right)=\sum_{d \mid n} \mu\left(\frac{n}{d}\right) 2^{d}-\sum_{d \mid n} \mu\left(\frac{n}{d}\right)=\sum_{d \mid n} \mu\left(\frac{n}{d}\right) 2^{d}
$$

But by dividing through $n$ (since every cycle of length $n$ contains $n$ elements) we get the desired formula.

Now looking back, we see that this argumentation doesn't work for the cycles of length 1 , but for these we can verify it directly.

## 10 Cycles under $x^{2}-2$ modulo $M_{q}$ prime

Theorem 4 (ZetaX-2) The number of cycles of length $L$ ( $L$ divides $q-1=$ $2^{s} u$ ) in the digraph $G_{x \rightarrow x^{2}-2}$ modulo a Mersenne prime $2^{q}-1$ is:

$$
\varsigma(L)=\frac{1}{L}\left(\sum_{d \mid L} \mu\left(\frac{L}{d}\right) 2^{d}-\sum_{2^{s}|d| L} \mu\left(\frac{L}{d}\right) 2^{d-1}\right)
$$

Definition: A primitive root is a $\zeta$, such that $\zeta^{k}, k \in\{1,2, \ldots, p-1\}$ gives all different prime residue classes $(\bmod p)$, so $\{1,2,3, \ldots, p-1\}$. They exist
modulo every power of an odd prime and some other cases and also in every finite field. Especially, they exist modulo ever prime $p$.

Now fix a primitive root $\zeta(\bmod p)$. Any prime residue class $x(\bmod p)$ can now be seen as some power $x \equiv \zeta^{k}(\bmod p)$ for suitable $k$. Since when also $y \equiv \zeta^{l}(\bmod p)$, it follows that $x y \equiv \zeta^{k} \zeta^{l}=\zeta^{k+l} \equiv \zeta^{(k+l)(\bmod p-1)}(\bmod p)$ (by Fermat's theorem), so you can see multiplication $(\bmod p)$ as addition $(\bmod p-1)$ (excluding 0$)$. So considering these powers $k, l$ is like taking logarithm in the real numbers.
But now back to the (less elementary !) problem concerning $x^{2}-2$ :

## Proof:

Let $p=2^{q}-1$ be a prime (so $q$ is also prime). Lets work in the field $\mathbb{F}_{p}$ or $\mathbb{F}_{p^{2}}$ respectively (so the field with $p$ elements and it's quadratic extension): Let $a_{0}, a_{1}, a_{2}, \ldots, a_{n}=a_{0}$ be a cycle (of length dividing $n$ ). When we can write $a_{0}=x+x^{-1}$, we would get by induction that $a_{k}=x^{2^{k}}+x^{-2^{k}}$ for all $k$. Such $x$ does not necessary exist in $\mathbb{F}_{p}$, but, since it is a quadratic equation, for sure in $\mathbb{F}_{p^{2}}$.
So $a=x+x^{-1}$ is part of a cycle of length dividing $n$ iff:

$$
\begin{aligned}
& x^{2^{n}}+x^{-2^{n}}=a_{n}=a_{0}=x+x^{-1} \\
& \Longleftrightarrow x^{2^{n+1}}-x^{2^{n}+1}-x^{2^{n}-1}+1=0 \\
& \Longleftrightarrow\left(x^{2^{n}+1}-1\right)\left(x^{2^{n}-1}-1\right)=0
\end{aligned}
$$

yielding two equations to solve in $\mathbb{F}_{p^{2}}$ (under the additional condition of $x+x^{-1} \in \mathbb{F}_{p}$ ):
(a) $x^{2^{n}+1}=1$
(b) $x^{2^{n}-1}=1$

Since $p^{2}-1=(p+1)(p-1)=2^{q+1}\left(2^{q-1}-1\right)$, all these solutions are already in $\mathbb{F}_{p}$ (because of order/primitive roots again).
Now that means we are looking for $x \in \mathbb{F}_{p}$ with $\operatorname{ord}(x) \mid 2^{n}+1$ or $\operatorname{ord}(x) \mid$ $2^{n}-1$.

Special case: $n \mid p-1$ and $n$ is odd.
Now also $2 n \mid p-1$, and (because of $2^{n}+1 ; 2^{n}-1\left|2^{2 n}-1\right| 2^{q-1}-1$ ) there are already all $2^{n}+1$ solutions for (a) and all $2^{n}-1$ solutions for (b) contained in $\mathbb{F}_{p}$ (this statement is again based on the existence of a primitive root).
The only solution to both equations is $x=1$. But when $x$ is a solution, also $x^{-1}$ is a solution, but $x$ and it's inverse (and only those, since a quadratic
equation has just two roots) give the same $a=x+x^{-1}$, and the only selfinverse $x$ are $\pm 1$ (and -1 is for sure not a solution, 1 is).
So there are exactly $\frac{2^{n}+1+2^{n}-1}{2}=2^{n}$ different such $a$. Now again using Moebius inversion gives the result for the odd $n$ dividing $q-1$.

## General case:

Let $k_{n}$ be the number of solutions of (a).
Let $l_{n}$ be the number of solutions of (b).
Then the number of cycles of length dividing $n$ is $\left(k_{n}+l_{n}\right) / 2$.
Now by the same reasons as before, we get that $k_{n}=\operatorname{gcd}\left(2^{n}+1,2^{q-1}-1\right)$ and $l_{n}=\operatorname{gcd}\left(2^{n}-1,2^{q-1}-1\right)$, thus, the problem is solved after using Moebius again.
Note that most of this arguing works for all primes, not just that of Mersenne type.

To simplify the formula, we just have to consider divisors of $q-1$ as length of cycles again, so let $n$ be a divisor of $q-1$ from now on.
Let $\psi(n)$ denote the number of elements that are part of a cycle of a length dividing $n$.
Claim:

$$
\psi(n)=\left\{\begin{array}{l}
2^{n} \text { iff } 2 n \mid q-1 \\
2^{n-1} \text { otherwise }
\end{array}\right.
$$

Proof:
Since $n \mid q-1$, we have $\operatorname{gcd}\left(2^{n}-1,2^{q-1}-1\right)=2^{n}-1$, so there are $2^{n}-1$ solutions for (b).
Since $2^{n}+1$ and $2^{n}-1$ are co-primes, we get:

$$
\begin{aligned}
\operatorname{gcd}\left(2^{n}+1,2^{q-1}-1\right) & =\frac{\operatorname{gcd}\left(2^{n}-1,2^{q-1}-1\right) \cdot \operatorname{gcd}\left(2^{n}+1,2^{q-1}-1\right)}{\operatorname{gcd}\left(2^{n}-1,2^{q-1}-1\right)} \\
& =\frac{\operatorname{gcd}\left(2^{2 n}-1,2^{q-1}-1\right)}{\operatorname{gcd}\left(2^{n}-1,2^{q-1}-1\right)} .
\end{aligned}
$$

Now if $2 n \mid q-1$, we get:

$$
\frac{\operatorname{gcd}\left(2^{2 n}-1,2^{q-1}-1\right)}{\operatorname{gcd}\left(2^{n}-1,2^{q-1}-1\right)}=\frac{2^{2 n}-1}{2^{n}-1}=2^{n}+1
$$

and there are $\left(2^{n}-1+2^{n}+1\right) / 2=2^{n}$ solutions then.
If otherwise $2 n \nmid q-1$, we get:

$$
\frac{\operatorname{gcd}\left(2^{2 n}-1,2^{q-1}-1\right)}{\operatorname{gcd}\left(2^{n}-1,2^{q-1}-1\right)}=\frac{2^{n}-1}{2^{n}-1}=1
$$

and there are $\left(2^{n}-1+1\right) / 2=2^{n-1}$ solutions then.
Now when $\varsigma(n)$ describes the number of cycles of length exactly $n$, we get that $n \cdot \varsigma(n)$ is the number of elements that are part of such a cycle and by Moebius we reach:

$$
n \cdot \varsigma(n)=\sum_{d \mid n} \mu\left(\frac{n}{d}\right) \psi(d)
$$

or equivalently:

$$
\varsigma(n)=\frac{1}{n} \sum_{d \mid n} \mu\left(\frac{n}{d}\right) \psi(d) .
$$

To write it without that cases, let $q-1=2^{s} u$, where $u$ is odd. Then the formula reduces to:

$$
\varsigma(n)=\frac{1}{n}\left(\sum_{2^{s} \backslash d \mid n} \mu\left(\frac{n}{d}\right) 2^{d}+\sum_{2^{s}|d| n} \mu\left(\frac{n}{d}\right) 2^{d-1}\right)
$$

and to:

$$
\varsigma(n)=\frac{1}{n}\left(\sum_{d \mid n} \mu\left(\frac{n}{d}\right) 2^{d}-\sum_{2^{s}|d| n} \mu\left(\frac{n}{d}\right) 2^{d-1}\right)
$$

Note that for the divisors of $\frac{q-1}{2}$ this is simply the formula from the $x^{2}$ case!
Here is the PARI/gp program that computes the number of cycles of length $L$ under $l l t(x)=x^{2}-2$ modulo a Mersenne number.
$H(q)=$
\{

```
s=0; while((q-1)%(2^s) == 0, s++); s--;
print("q= ", q, " = 1 + 2^", s, ".", (q-1)/2^s, "\n");
dq = divisors(q-1);
ldq = length(dq);
print("L= ", 1, " -> 1");
for(j=2, ldq,
    n = dq[j];
    dn = divisors(n);
    ldn = length(dn);
    S = 0;
```

```
    for(i=1, ldn,
    ddn = dn[i];
        S += moebius(n/ddn)*2^(ddn);
    if(ddn%(2^s) == 0,
        S -= moebius(n/ddn)*2^(ddn-1);
    );
    );
    if(S != 0, print("L= ", n, " -> ", S/n););
    );
    print("\n");
}
```

## 11 Another proof by maxal (GIMPS forum)

One can show that the cycles in the LLT Digraph under the mapping $x \rightarrow$ $x^{2}-2$ correspond to the cycles in the group $Z_{2^{q-1}-1}$ under the mapping $x \rightarrow 2 x$ where elements $x$ and $-x$ are considered the same.

For example, let $q=5$. Then in $Z_{15}$ we have the following cycles:
$0 \rightarrow 0$
$1 \rightarrow 2 \rightarrow 4 \rightarrow 8 \rightarrow 1$
$3 \rightarrow 6 \rightarrow 12 \rightarrow 9 \rightarrow 3$
$5 \rightarrow 10 \rightarrow 5$
$7 \rightarrow 14 \rightarrow 13 \rightarrow 11 \rightarrow 7$
If elements $x$ and $-x$ are considered the same then we have the following cycles:
$0 \rightarrow 0$
$1 \rightarrow 2 \rightarrow 4 \rightarrow 8 \rightarrow 1$ and $7 \rightarrow 14 \rightarrow 13 \rightarrow 11 \rightarrow 7$ represent the same cycle.
$3 \rightarrow 6 \rightarrow 12 \rightarrow 9 \rightarrow 3$ becomes $3 \rightarrow 6 \rightarrow-3$
$5 \rightarrow 10 \rightarrow 5$ becomes $5 \rightarrow-5$
i.e., there are two 1 -cycles, one 2 -cycle, and one 4 -cycle.

We call conjugate cycles containing $x$ and $-x$ for some $x$. In the example above, $1 \rightarrow 2 \rightarrow 4 \rightarrow 8 \rightarrow 1$ and $7 \rightarrow 14 \rightarrow 13 \rightarrow 11 \rightarrow 7$ are conjugate cycles while $3 \rightarrow 6 \rightarrow 12 \rightarrow 9 \rightarrow 3$ is self-conjugate cycle.

Denote by $c(k)$ the number of k -cycles in $Z_{2^{q-1}-1}$ and by $c^{\prime}(k)$ the number of self-conjugate k-cycles. Then the number of k-cycles in the LLT Digraph is $C(k)=\left(c(k)-c^{\prime}(k)\right) / 2+c^{\prime}(2 k)$. (Gluing each pair of elements $x$ and $-x$ into a single one contracts the cycles in $Z_{2^{q-1}-1}$. The contracted k-cycles are formed by: 1) pairs of conjugate k-cycles which glue into a single k-cycle
under the contraction. The number of such pairs is $\left.\left(c(k)-c^{\prime}(k)\right) / 2.2\right)$ selfconjugate 2 k -cycles which shrink their length by the factor of 2 under the contraction. The number of such cycles is $\left.c^{\prime}(2 k)\right)$.

For $q=5$ we have $c(1)=2, c(2)=1, c(4)=3$ and $c^{\prime}(1)=0, c^{\prime}(2)=1$, $c^{\prime}(4)=1$ implying $C(1)=2, C(2)=1, C(4)=1$.

It is easy to see that $c(k)=\sum_{d \mid k} \mu(k / d)\left(2^{d}-1\right) / k$ if $k$ divides $(q-1)$, and $c(k)=0$ otherwise.

Similarly, one can show that

1) for odd $s, c^{\prime}(s)=0$ except $c^{\prime}(1)=1$.
2) for odd $s$ and for $t>=1$ such that $2^{t} s$ divides $(q-1), c^{\prime}\left(2^{t} s\right)=\sum_{d \mid s} \mu(s / d) 2^{2^{t-1} d} /\left(2^{t} s\right)$ for $t>=1$ and odd $s$.
$3)$ for odd $s$ and for $t>=1$ such that $2^{t} s$ does not divide $(q-1), c^{\prime}\left(2^{t} s\right)=0$.
In order to simplify things consider two functions that do not depend on q : $c 1(k)=\sum_{d \mid k} \mu(k / d)\left(2^{d}-1\right) / k c 2\left(2^{t} s\right)=\sum_{d \mid s} \mu(s / d) 2^{2^{t-1} d} /\left(2^{t} s\right)$ for $t>=1$ and odd $s$, and $c 2(k)=0$ for odd $k>1$ and $c 2(1)=1$.
It can be shown that $c 2(2 m)=(c 1(m)+c 2(m)) / 2$ and, thus, $(c 1(k)-$ $c 2(k)) / 2+c 2(2 k)=c 1(k)$.

Now let's compute the number of k-cycles in the LLT Digraph for $k$ dividing $(q-1)$. For such $k$, we have $c(k)=c 1(k)$ and $c^{\prime}(k)=c 2(k)$ but not necessary $c^{\prime}(2 k)=c 2(2 k)$ since $2 k$ may not divide $(q-1)$. This happens when $(q-1) / k$ is odd number in which case the summand $c 2(2 k)$ happens to be excessive implying $C(k)=c 1(k)-c 2(2 k)$.

Therefore, $C(k)=0$ if $k$ does not divide $(q-1), C(k)=c 1(k)$ if $k$ divides $(q-1)$ and $(q-1) / k$ is even number, $C(k)=c 1(k)-c 2(2 k)=(c 1(k)-c 2(k)) / 2$ if $k$ divides $(q-1)$ and $(q-1) / k$ is odd number.

## Properties:

$C(k)=0$ if $k$ does not divide $(q-1)$.
$C(k)=c 1(k)$ if $k$ divides $(q-1)$ and $(q-1) / k$ is even number.
$C(k)=c 1(k)-c 2(2 k)=(c 1(k)-c 2(k)) / 2$ if $k$ divides $(q-1)$ and $(q-1) / k$ is odd number.
$c 1(k)=A 059966(k)$
$c 2(2 k)=A 000048(k)$
$c 1(k)-c 2(2 k)=A 051841(k)$

Table 5: Number of cycles of length $L$ under $x^{2}-2$ modulo the first Mersennes composites. (r:real t:theoretical)

## 14 Ratio $\left(M_{q}-1\right) / \operatorname{order}\left(3, M_{q}\right)$

Let call: $\eta(q, b)$ the number of distinct numbers $b^{n}+1 / b^{n}\left(\bmod M_{q}\right)$ for $q$, and $\theta(q, b)=\frac{M_{q-1}}{\eta(q, b)}$.
Let call: $\rho(q, b)=\frac{M_{q}-1}{\operatorname{order}\left(b, M_{q}\right)}$.
The table 6 shows that there is a relationship between $\eta(q, b)$ and $\rho(q, b)$ :
For $q=3,5,7,17,19$ we have: $\operatorname{order}(3, M q) / \eta(q, 3)=2$.
For $q=13,31$ we have: $(\operatorname{order}(3, M q)+2) / \eta(q, 3)=2$.

## $152 \eta\left(3, M_{q}\right)=\operatorname{order}\left(3, M_{q}\right)+2$ Proof by ZetaX

Let $p$ be any odd prime. Let $f(x):=x+\frac{1}{x} \bmod p$, then we want the size (lets call it $\eta(k, p)$ ) of the set $\left\{f\left(k^{n}\right) \mid n \in \mathbb{N}\right\}$.
First lets find out how often $f(x) \equiv f(y) \bmod p$ with $x, y \not \equiv 0 \bmod p$ happens: This means $x+\frac{1}{x} \equiv y+\frac{1}{y} \bmod p \Longleftrightarrow x^{2} y+y \equiv x y^{2}+x \bmod p$ $\Longleftrightarrow(x y-1)(x-y) \equiv 0 \bmod p$. This means that either $x \equiv y \bmod p$, the trivial case, or $x y \equiv 1 \bmod p$. But: when $x \equiv \pm 1 \bmod p$, then only the case $x \equiv y \bmod p$ can occur.

| q | $\theta(q, 3)$ | $\theta(q, q)$ | $\theta(q, 3 q)$ | $\theta(q, 6 q)$ | $\rho(q, 3)$ | $\rho(q, q)$ | $\rho(q, 3 q)$ | $\rho(q, 6 q)$ |

| 1279 |  |  |  |  | 3 | 1 | 2 | 2 |

## Table 6: .

Look at the set $\operatorname{Pow}(k):=\left\{k^{n} \bmod p \mid n \in \mathbb{Z}\right\}$ (we can use $\mathbb{Z}$ instead of $\mathbb{N}$ because of Fermat's Little Theorem). It has size $|\operatorname{Pow}(k)|=\operatorname{ord}(k, p)$. Additionally, we can pair up the elements $k^{n} \bmod p$ and $k^{-n} \bmod p$ for each $n$, since they give the same value $f\left(k^{n}\right) \equiv f\left(k^{-n}\right) \bmod p$, and only those are equal (note that $1,-1 \bmod p$ will be left alone, but each noted as "pair" with one element). Since different pairs give different values, we have that $\eta(k, p)=$ "number of such pairs". Thus when $-1 \in \operatorname{Pow}(k)(1$ is always in the set), there will be $\frac{\operatorname{ord} d(k, p)-2}{2}+2=\frac{\operatorname{ord}(k, p)+2}{2}$ pairs, thus by the above $\eta(k, p)=\frac{\operatorname{ord}(k, p)+2}{2} \Longleftrightarrow 2 \eta(k, p)=\operatorname{ord}(k, p)+2$. Similar when -1 is not in the set: $2 \eta(k, p)=\operatorname{ord}(k, p)+1$
This for example gives $\eta(3,7)=4$.
To find out if -1 is in the set, we need to know if the order of $k \bmod p$ is even or odd (this suffices to know: when ord $(k, p)$ would be odd, we couldn't have $2 \eta(k, p)=\operatorname{ord}(k, p)+2 \bmod 2$, and analogous for the other case). When $s$ is the biggest integer with $2^{s} \mid p-1$, we could calculate $k^{\frac{p-1}{2^{s}}} \bmod p$ (since $\frac{p-1}{2^{s}}$ is the biggest odd divisor of $p-1$ ) and look if it is $1 \bmod p$ or not (the order is odd iff it is $1 \bmod p$ ). When $4 \nmid p-1$, we just ask whether $k$ is a quadratic residue $\bmod p$ or not, which can be checked by Jacobi symbols. Special case $k=3, p=2^{q}-1$ : Then $4 \nmid p-1$, thus we use Legendre symbols (Jacobi is not needed since both numbers are prime) and the law of quadratic
reciprocity: $\left(\frac{3}{2^{q}-1}\right)=-\left(\frac{2^{q}-1}{3}\right)=-1$. This shows that the order of $3 \bmod p$ is even. Thus for Mersenne primes $p=M_{q}$, it is: $2 \eta(3, p)=\operatorname{ord}(3, p)+2$.

## 16 Conjecture: $\frac{M_{q}-1}{\operatorname{order}\left(3, M_{q}\right)}=3^{n}$ with $n=0,1,2$

Based on the data in table 7, we have the conjecture:

$$
\frac{M_{q}-1}{\operatorname{order}\left(3, M_{q}\right)}=3^{n} \quad \text { with } \quad n=0,1,2
$$

It seems that the conjecture is wrong for: $q=3217$. But I do not understand the explanation ...

| q | $\left(M_{q}-1\right) / \operatorname{order}\left(3, M_{q}\right)$ |

## 17 Loops under $x^{3}-3 x$ Modulo a Mersenne

I computed the number of cycles of length $L$ for $q=3,5,7,13,17,19,31$, as shown in Table 9, by means of a C program that computes all pairs $\left(x, x^{3}-3 x\right.$ $\left.\left(\bmod M_{q}\right)\right)$, finds the cycles and counts cycles of same length.
There are at least 1 cycle of length $2^{i}$, for $i=0 \ldots q-2$. They are related to the tree under $x^{2}-2$ and do not appear here below, for the $q$ such that $M_{q}$ is prime.

| $L=$ | 1 | 2 | 3 | $\mathbf{4}$ | 5 | 6 | $\mathbf{8}$ | 9 | 10 | 12 | 15 | $\mathbf{1 6}$ | 18 | 36 | 128 | 256 |

| 31 | 2 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 8: Number of cycles of length $L$ under $x^{3}-3 x$ modulo the first Mersennes, without the cycles related to the tree under $x^{2}-2$.

We name $C_{q, n, l}$ a cycle of length $l$ under the $l l t$ function of degree $n$, modulo the Mersenne prime $M_{q}=2^{q}-1$.
We recall that $l l t_{0}: x \mapsto 2, l l t_{1}: x \mapsto x, l l t_{2}: x \mapsto x^{2}-2, l l t_{3}: x \mapsto x^{3}-3 x$. For $q=7$, there are 2 cycles $C_{7,2,3}$ and 4 cycles $C_{7,2,6}$. Under $x^{3}-3 x, 3$ of the $C_{7,2,6}$ are connected to the 4 th cycle $C_{7,2,6}$; and this cycle is connected to one of the $C_{7,2,3}$, which is connected to it-self. The second cycle $C_{7,2,3}$ is connected to node 126 , which is connected to node 2 , connected to it-self.

## 18 Loops under $x^{2}-2$ Modulo a Fermat

| $L=$ | 1 | 3 | 5 | 7 | 15 |
| ---: | ---: | ---: | ---: | ---: | ---: |

| 1 | 2 |  |  |  |  |
| 2 | 2 | 1 |  |  |  |
| 3 | 2 |  |  | 9 |  |
| 4 | 2 | 1 | 3 |  | 1091 |

Table 9: Number of cycles of length $L$ under $x^{2}-2$ modulo the first Fermat primes.

Obviously, the length of cycles divide $2^{n}-1$.
Looking at OEIS, this looks like the following suites: A000048 (and A056303, A114702), A060172, A066313, A060481.
2 formulae:

$$
\begin{aligned}
& \psi(L)=\frac{1}{2 L} \sum_{\text {odd } d \mid L} \mu(d) 2^{\frac{L}{d}} \\
& \psi(L)=\frac{1}{L} \sum_{d \mid L} \mu(d) a\left(\frac{L}{d}\right)
\end{aligned}
$$
